Bulk evolution of heavy ion collisions in the beam energy scan: New developments and first results

Björn Schenke, Brookhaven National Laboratory
in collaboration with *Akihiko Monnai* (RBRC)

September 30 2015
Quark Matter 2015
Kobe, Japan

Introduction

Low energy collisions demand improvements of existing hydrodynamic simulations, including:

- Net-baryon current ✓
- Equation of state at finite baryon chemical potential ✓
- Initial state with fluctuating baryon- and entropy-density ✓
- Fluctuations in all three spatial dimensions ✓

- Baryon diffusion (to do)
- Strangeness and electric currents (to do)

Will show

- momentum and rapidity distributions at different energies
- rapidity dependent flow and the effect of $(\eta/s)(T)$
- two-particle pseudo rapidity correlations (of $h^{+/-}$ and net-baryons)

Hydrodynamics

Use the state of the art 3+1D viscous relativistic hydrodynamics **MUSIC** with **shear** and **bulk** viscosity and all nonlinear terms that couple bulk viscous pressure and shear-stress tensor

Solve $\partial_\mu T^{\mu\nu} = 0$ and $\partial_\mu J_B^\mu = 0$ along with

bulk shear

$$\tau_\Pi \dot{\Pi} + \Pi = -\zeta\theta - \delta_{\Pi\Pi}\Pi\theta + \lambda_{\Pi\pi}\pi^{\mu\nu}\sigma_{\mu\nu}$$

$$\tau_\pi \dot{\pi}^{\langle\mu\nu\rangle} + \pi^{\mu\nu} = 2\eta\sigma^{\mu\nu} - \delta_{\pi\pi}\pi^{\mu\nu}\theta + \varphi_7 \pi_\alpha^{\langle\mu}\pi^{\nu\rangle\alpha} - \tau_{\pi\pi}\pi_\alpha^{\langle\mu}\sigma^{\nu\rangle\alpha} + \lambda_{\pi\Pi}\Pi\sigma^{\mu\nu}$$

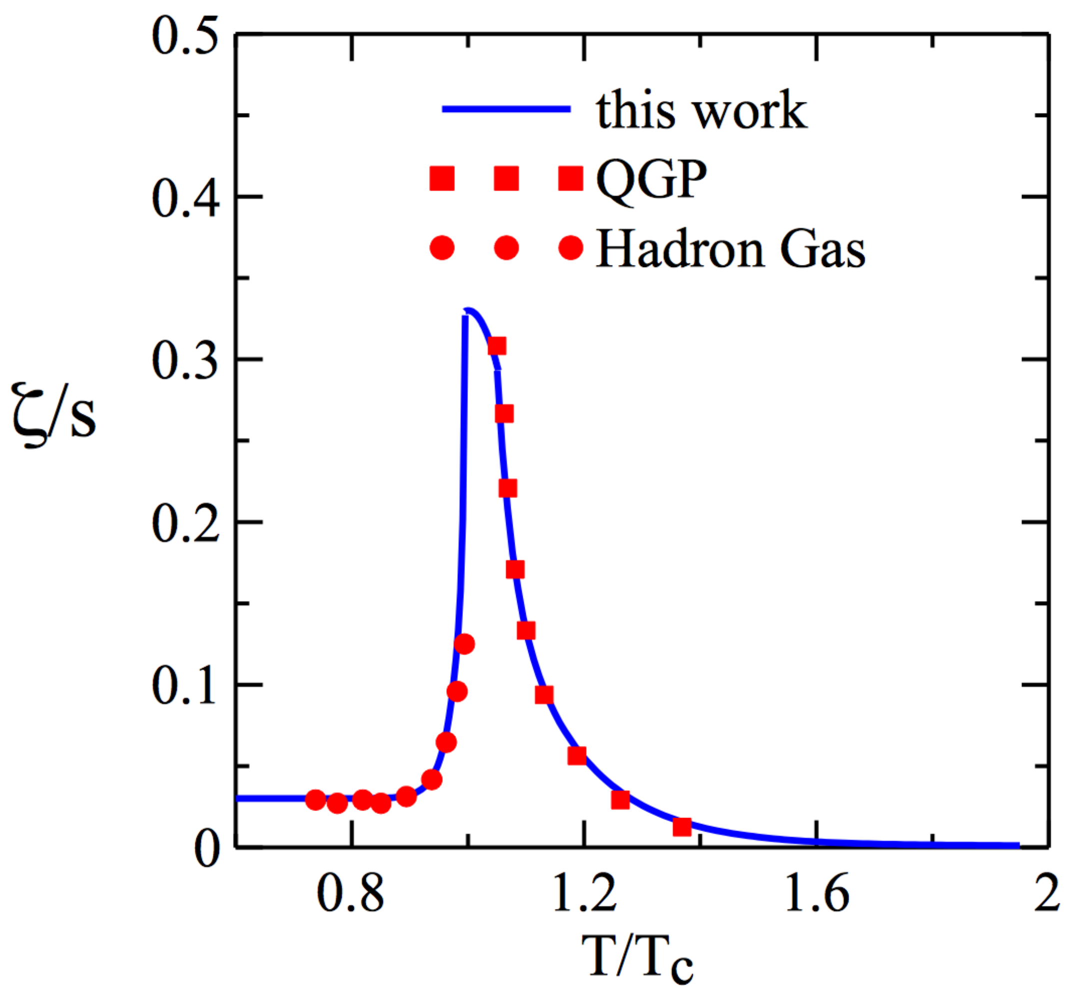
The transport coefficients $\tau_\Pi, \delta_{\Pi\Pi}, \lambda_{\Pi\pi}, \tau_\pi, \delta_{\pi\pi}, \phi_7, \tau_{\pi\pi}, \lambda_{\pi\Pi}$ are fixed using formulas derived from the Boltzmann equation near the conformal limit

G. S. Denicol, S. Jeon and C. Gale, Phys. Rev. C 90, 024912 (2014)
B. Schenke, S. Jeon, C. Gale, Phys. Rev. C82, 014903 (2010); Phys. Rev. Lett. 106, 04230 (2011)

Viscosities

In the calculations presented here we use:

- shear viscosity (constant or with T dependence to be defined)
- bulk viscosity:



S. Ryu, J. -F. Paquet, C. Shen, G.S. Denicol, B. Schenke, S. Jeon, C. Gale Phys.Rev.Lett. 115 (2015) 13, 132301

G. S. Denicol, U. W. Heinz, M. Martinez, J. Noronha and M. Strickland, Phys. Rev. D 90, 125026 (2014); Phys. Rev. Lett. 113, 202301 (2014)

QGP: F. Karsch, D. Kharzeev and K. Tuchin, Phys. Lett. B 663, 217 (2008)
Hadron Gas:
J. Noronha-Hostler, J. Noronha and C. Greiner, Phys. Rev. Lett. 103, 172302 (2009)

To reduce the sensitivity to δf corrections at high p_T we have the low T value drop exponentially

Equation of state

Construct EoS at finite μ_B using Taylor expanded lattice data:

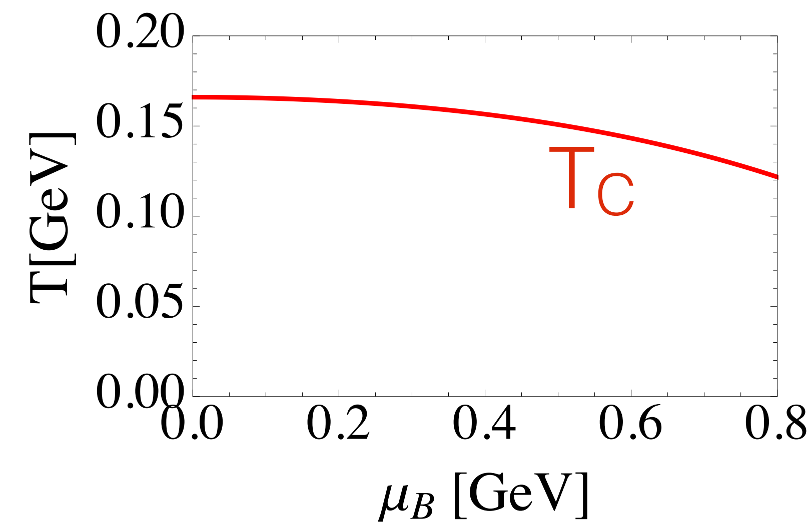
Hadron resonance gas

Lattice QCD

interpolate

connect smoothly at T_C

(**c**onnecting temperature)



$$\frac{P}{T^4} = \frac{P_0}{T^4} + \frac{1}{2}\chi_B^{(2)}\left(\frac{\mu_B}{T}\right)^2 + \frac{1}{4!}\chi_B^{(4)}\left(\frac{\mu_B}{T}\right)^4 + \mathcal{O}\left[\left(\frac{\mu_B}{T}\right)^6\right]$$

Currently using data for parameters P_0^{lat} and $\chi_B^{(2)}$ from:

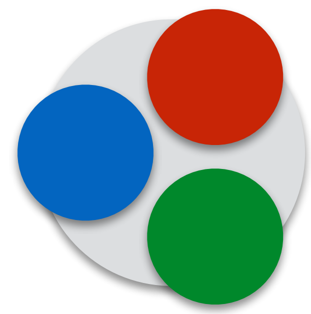
Borsanyi et al, JHEP1011, 077 (2010); JHEP1201, 138 (2012)

$\chi_B^{(4)}$ from the ratio $\chi_B^{(4)}/\chi_B^{(2)}$ in a HRG and parton gas model

Initial conditions - 3DMC-Glauber with quarks

Introduce a **simple** extension of the Monte Carlo Glauber model

We use constituent quarks



Constituent quark initial positions in the transverse plane are sampled from a 2D exponential distribution around the nucleon center (Nucleons are sampled from Woods-Saxon)

Their rapidities are sampled from nuclear parton distribution functions (in this talk we will use CTEQ10 and EPS09)

Their cross sections can be determined geometrically to reproduce the nucleon-nucleon cross sections

Event-by-event baryon density

Transverse distribution:

Implement black disk and Gaussian wounding to determine wounded quarks

Longitudinal distribution:

Implement an MC version of the **Lexus** model

S. Jeon and J. Kapusta, PRC56, 468 (1997)

Idea: Rapidity distributions in heavy ion collisions follow via linear extrapolation from p+p collisions

Distribution in p+p collisions is parametrized and fit to data

Probability for a quark with rapidity y_P to get rapidity y after collision with another quark with rapidity y_T:

$$Q(y, y_P, y_T) = \lambda \frac{\cosh(y - y_T)}{\sinh(y_P - y_T)} + (1 - \lambda)\delta(y - y_P)$$

where we treat λ as a free parameter

(it characterizes the stopping power for quarks)

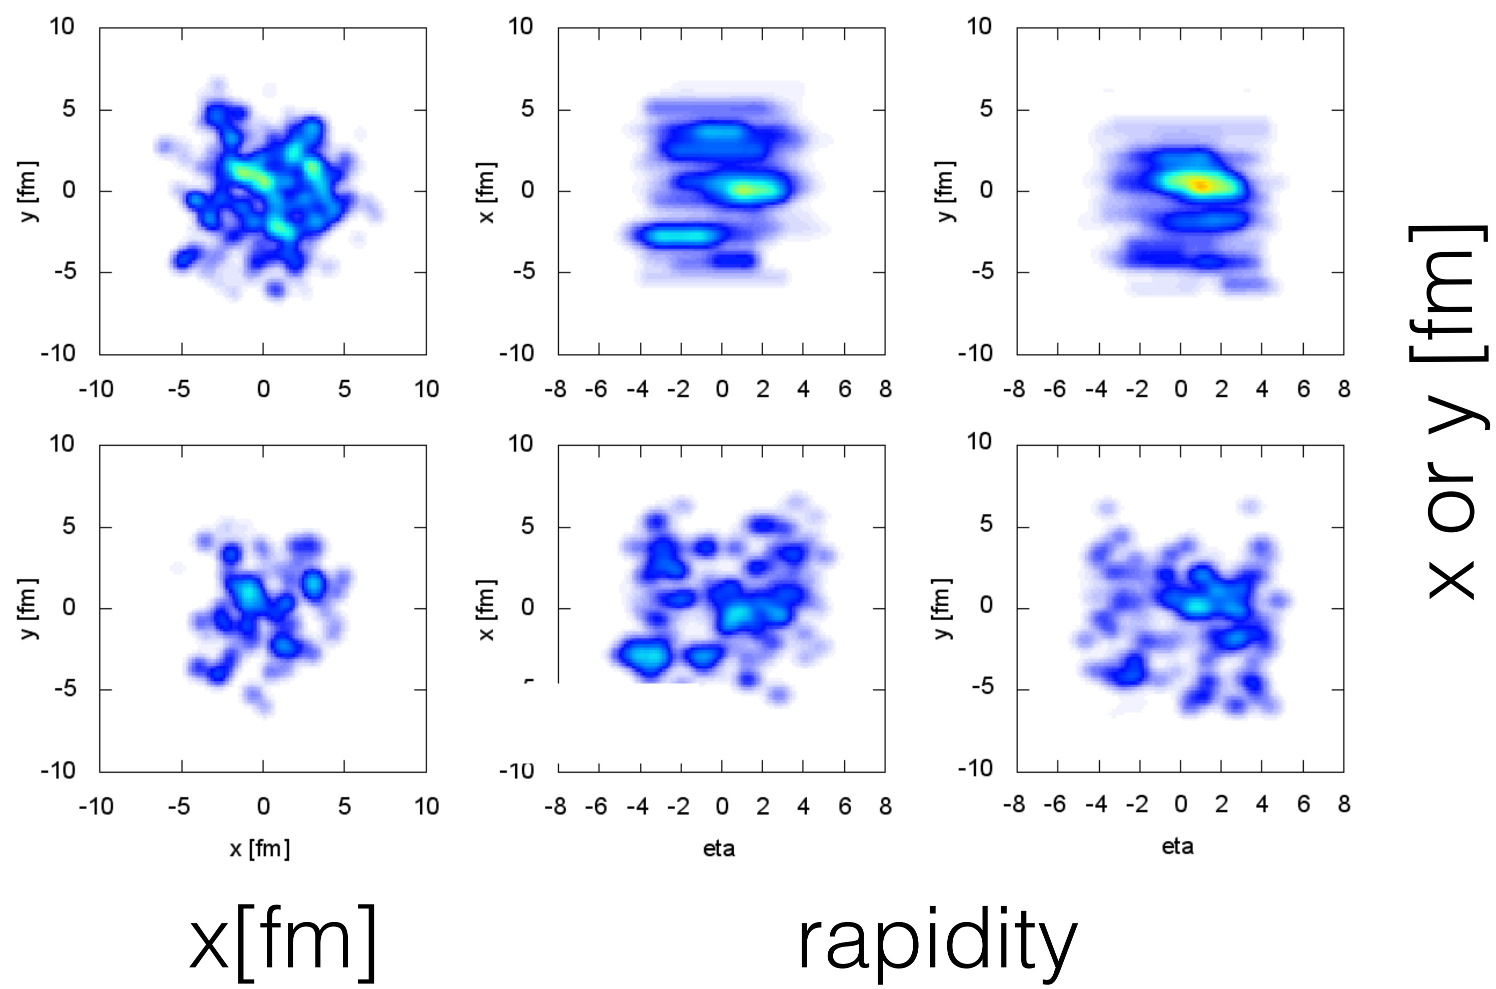
Event-by-event baryon- and entropy density

Deposit entropy density (fluctuating with NBD) between the collided constituent quarks using a Gaussian profile in the transverse plane and a constant distribution (with Gaussian edges) in rapidity

$\sqrt{s} = 200\mathrm{GeV}$

energy density

baryon density



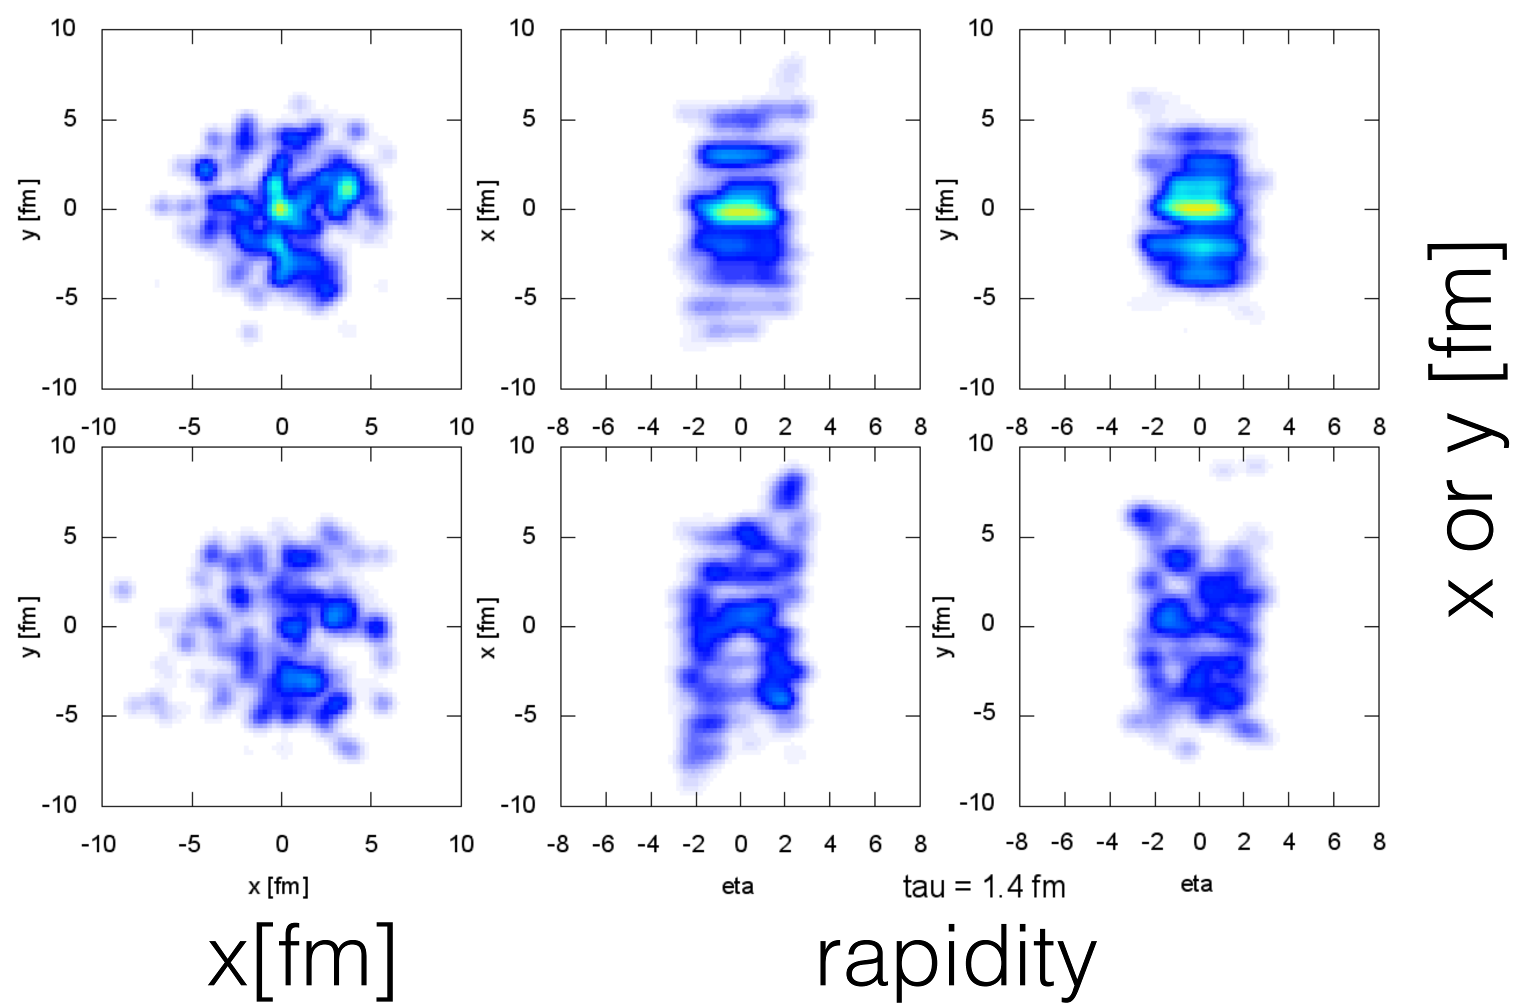
Event-by-event baryon- and entropy density

Deposit entropy density (fluctuating with NBD) between the collided constituent quarks using a Gaussian profile in the transverse plane and a constant distribution (with Gaussian edges) in rapidity

$\sqrt{s} = 19.6\mathrm{GeV}$

energy density

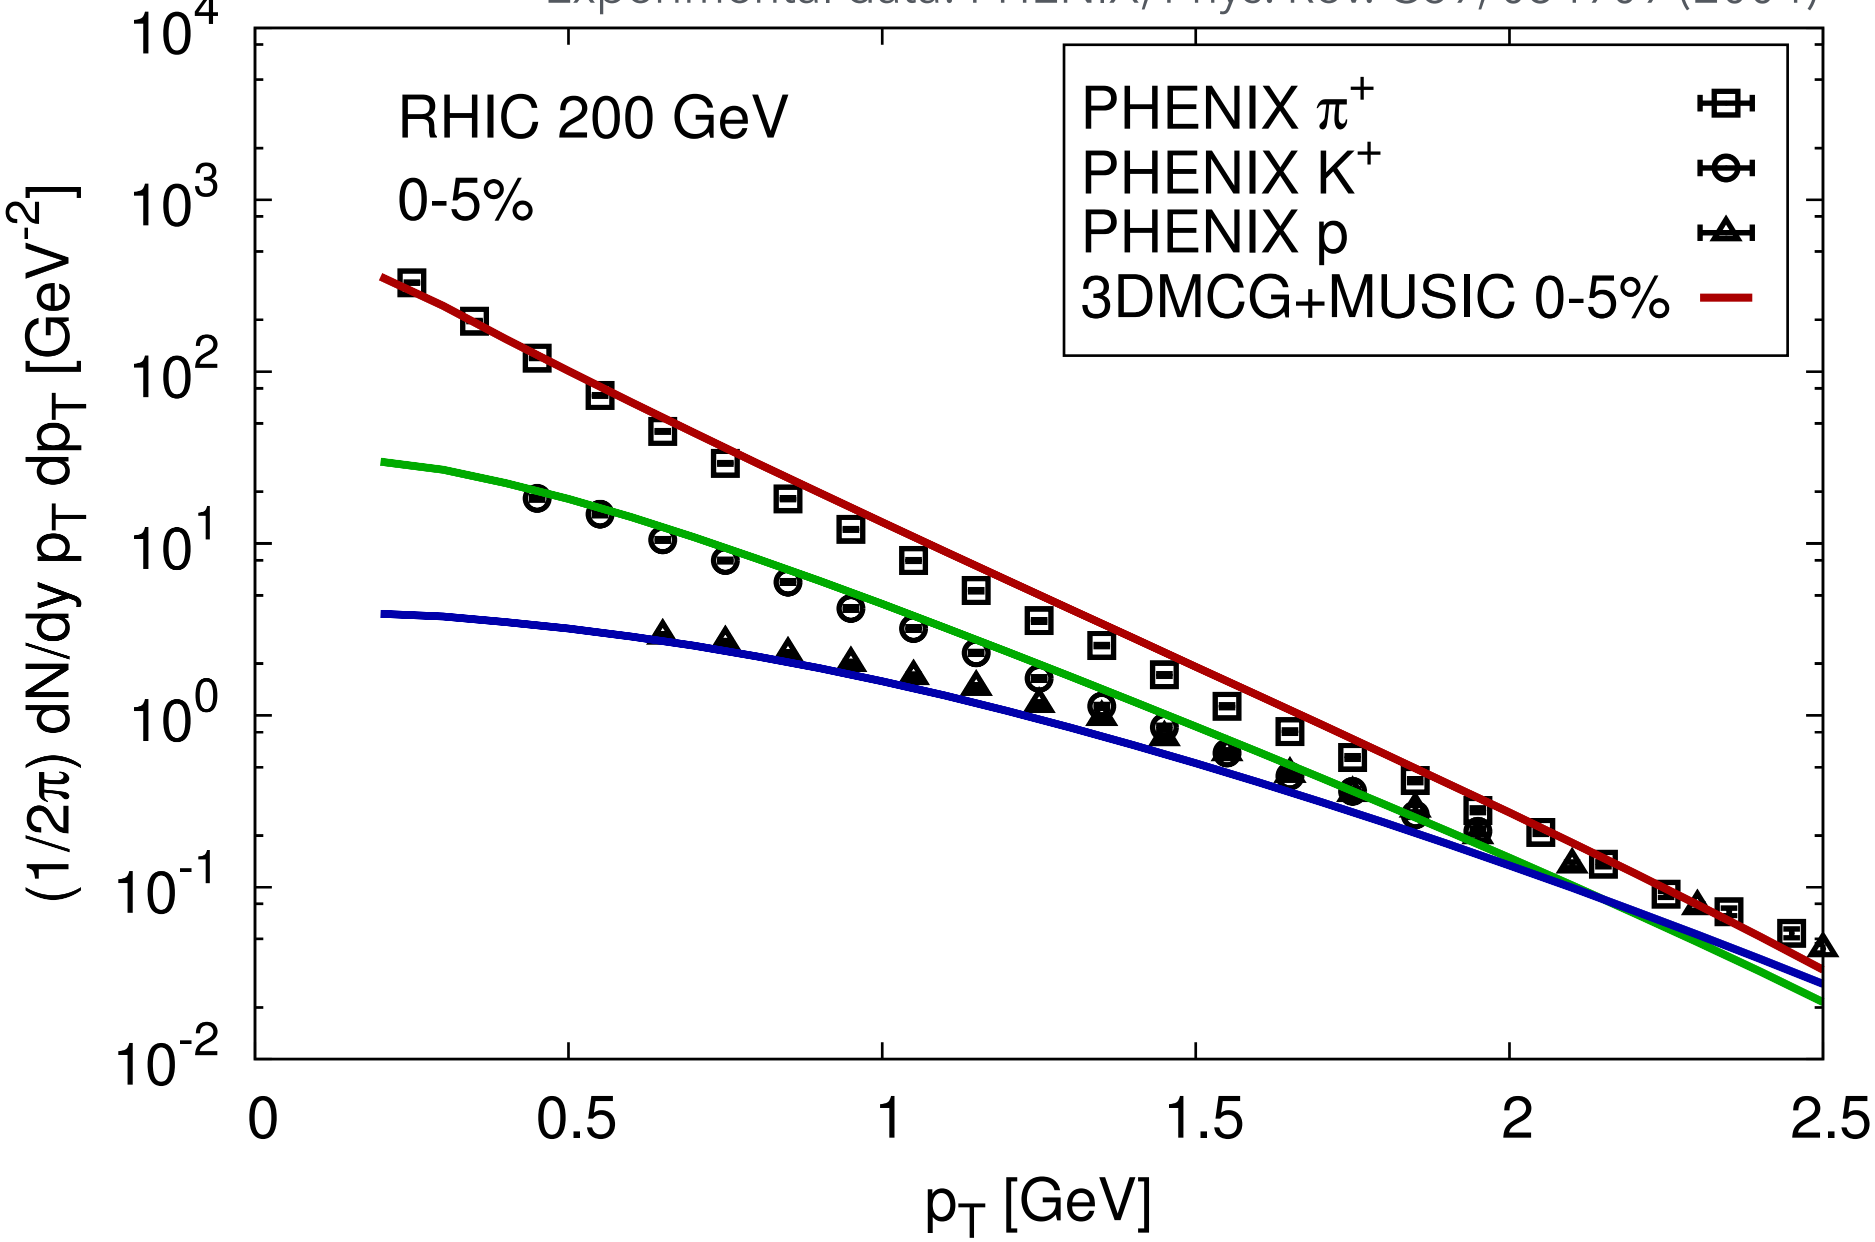
baryon density



Results

Identified particle transverse momentum spectra

Experimental data: PHENIX, Phys. Rev. C69, 034909 (2004)

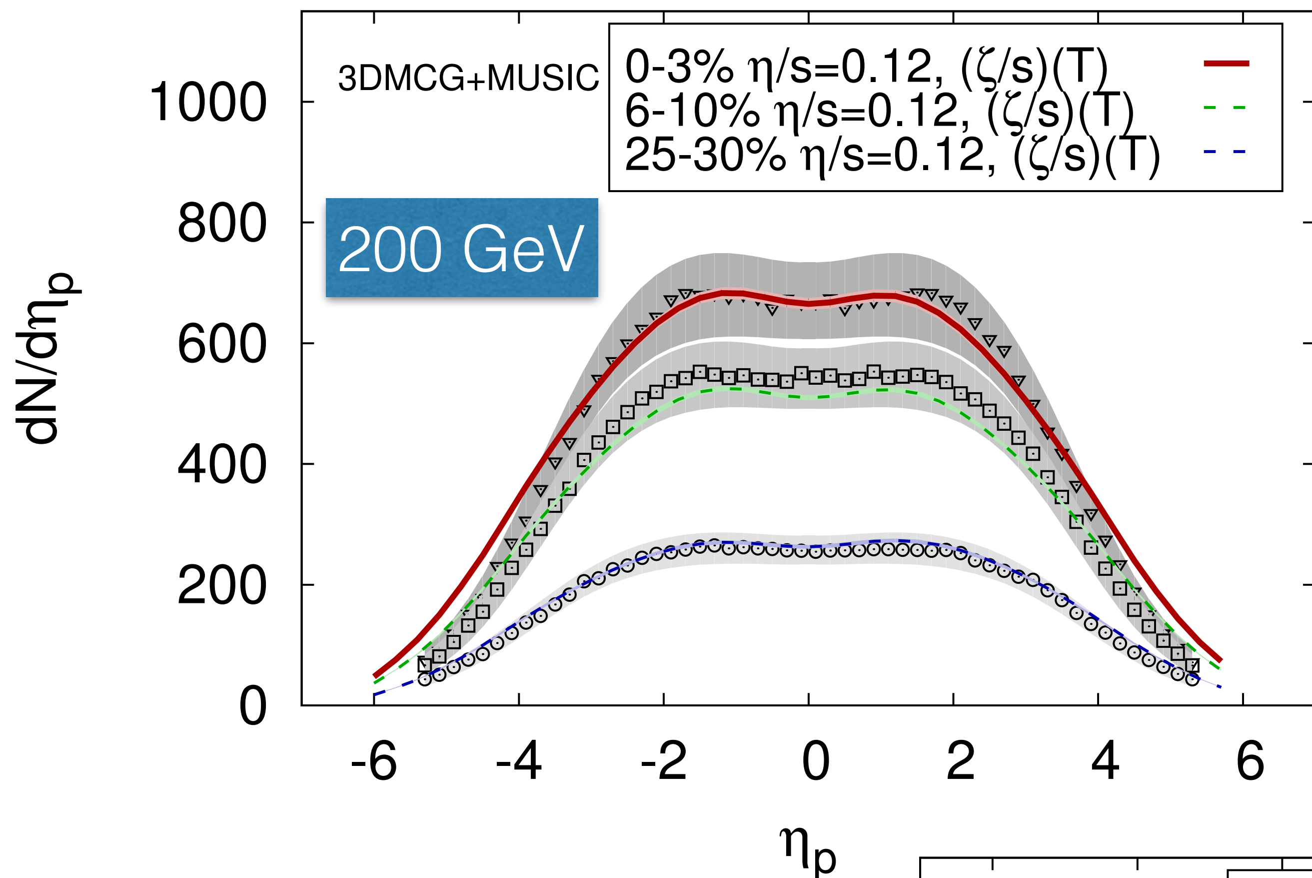


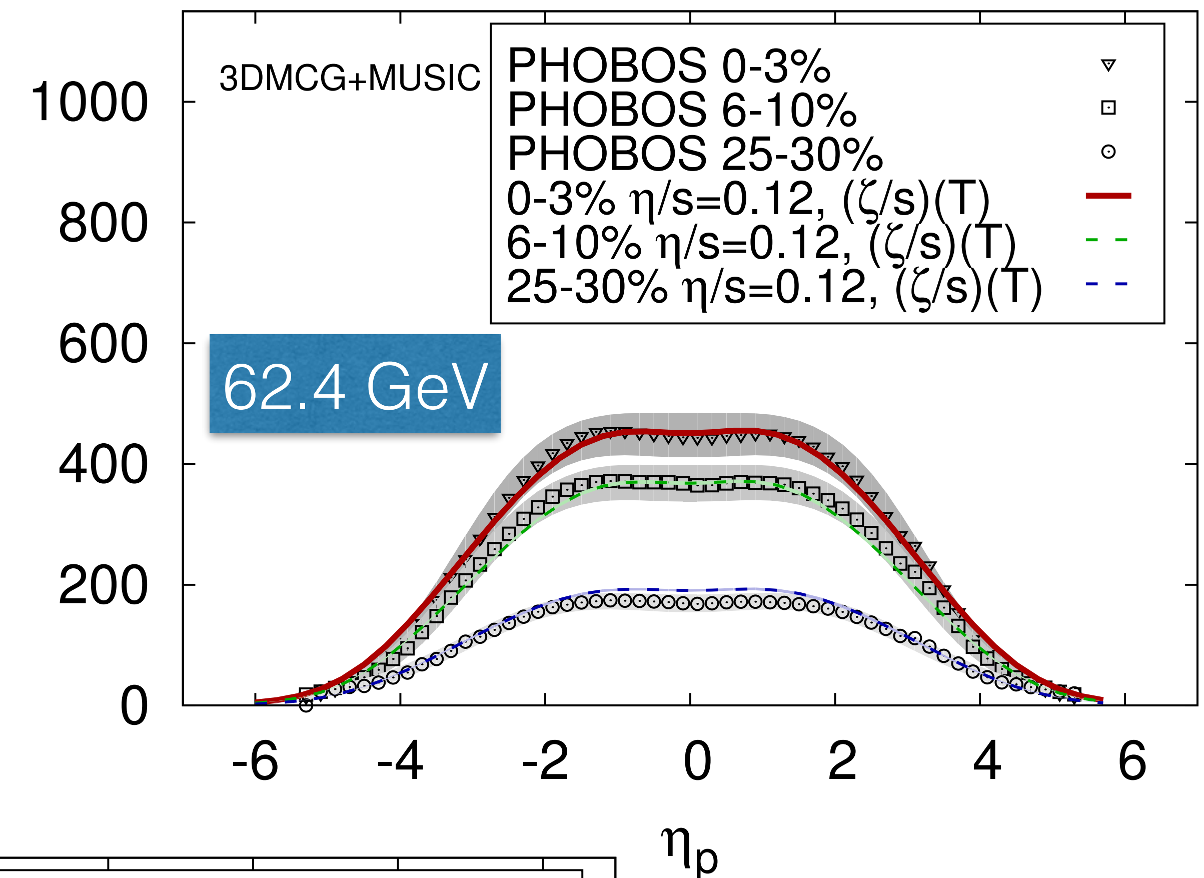
Bulk viscosity needed to get mean p_T right

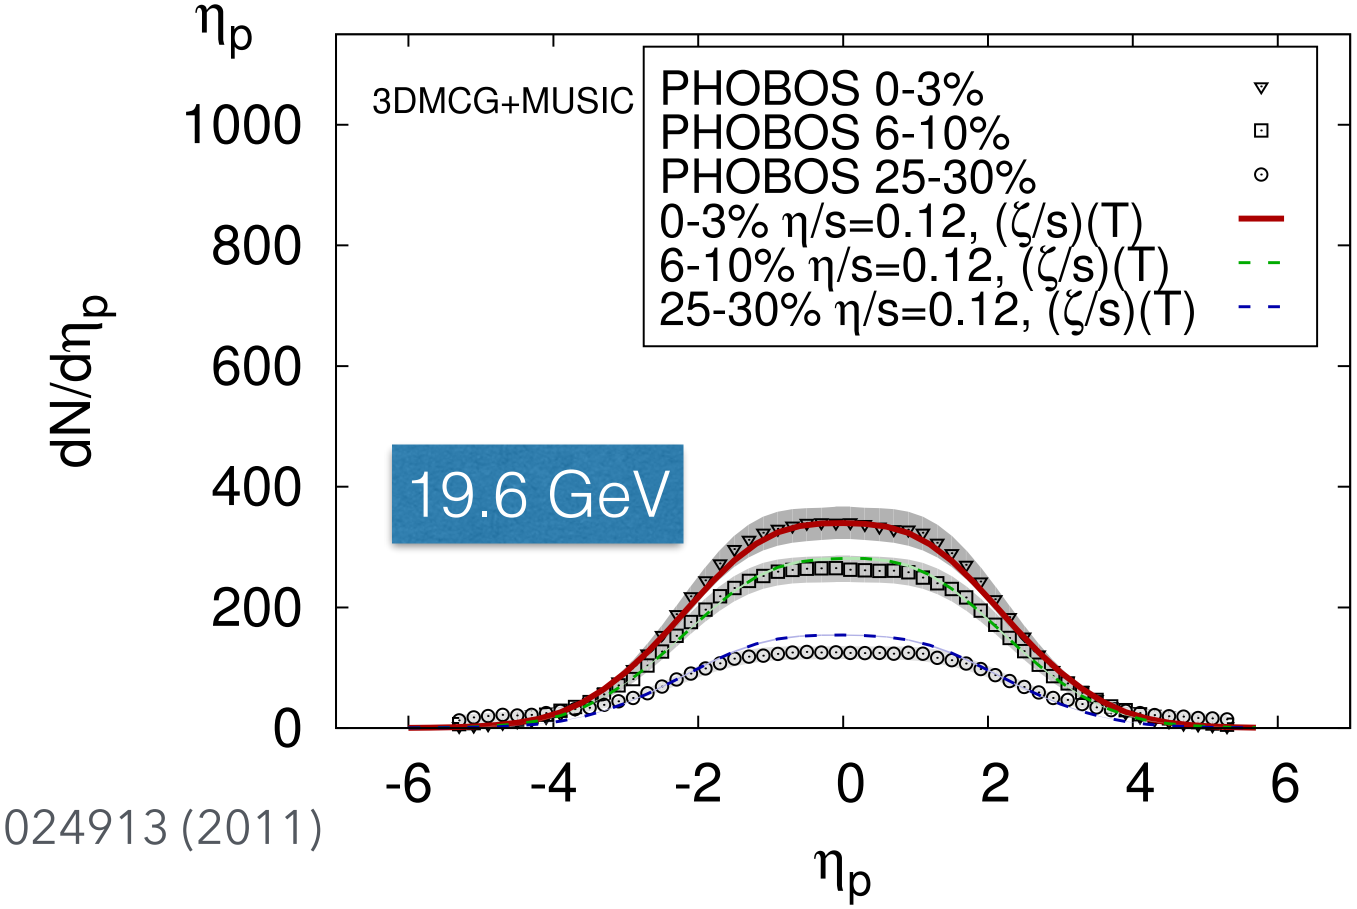
Same as with IP-Glasma initial conditions:

S. Ryu, J. -F. Paquet, C. Shen, G.S. Denicol, B. Schenke, S. Jeon, C. Gale, Phys. Rev. Lett. 115, 132301 (2015)

Charged hadron pseudo-rapidity distributions

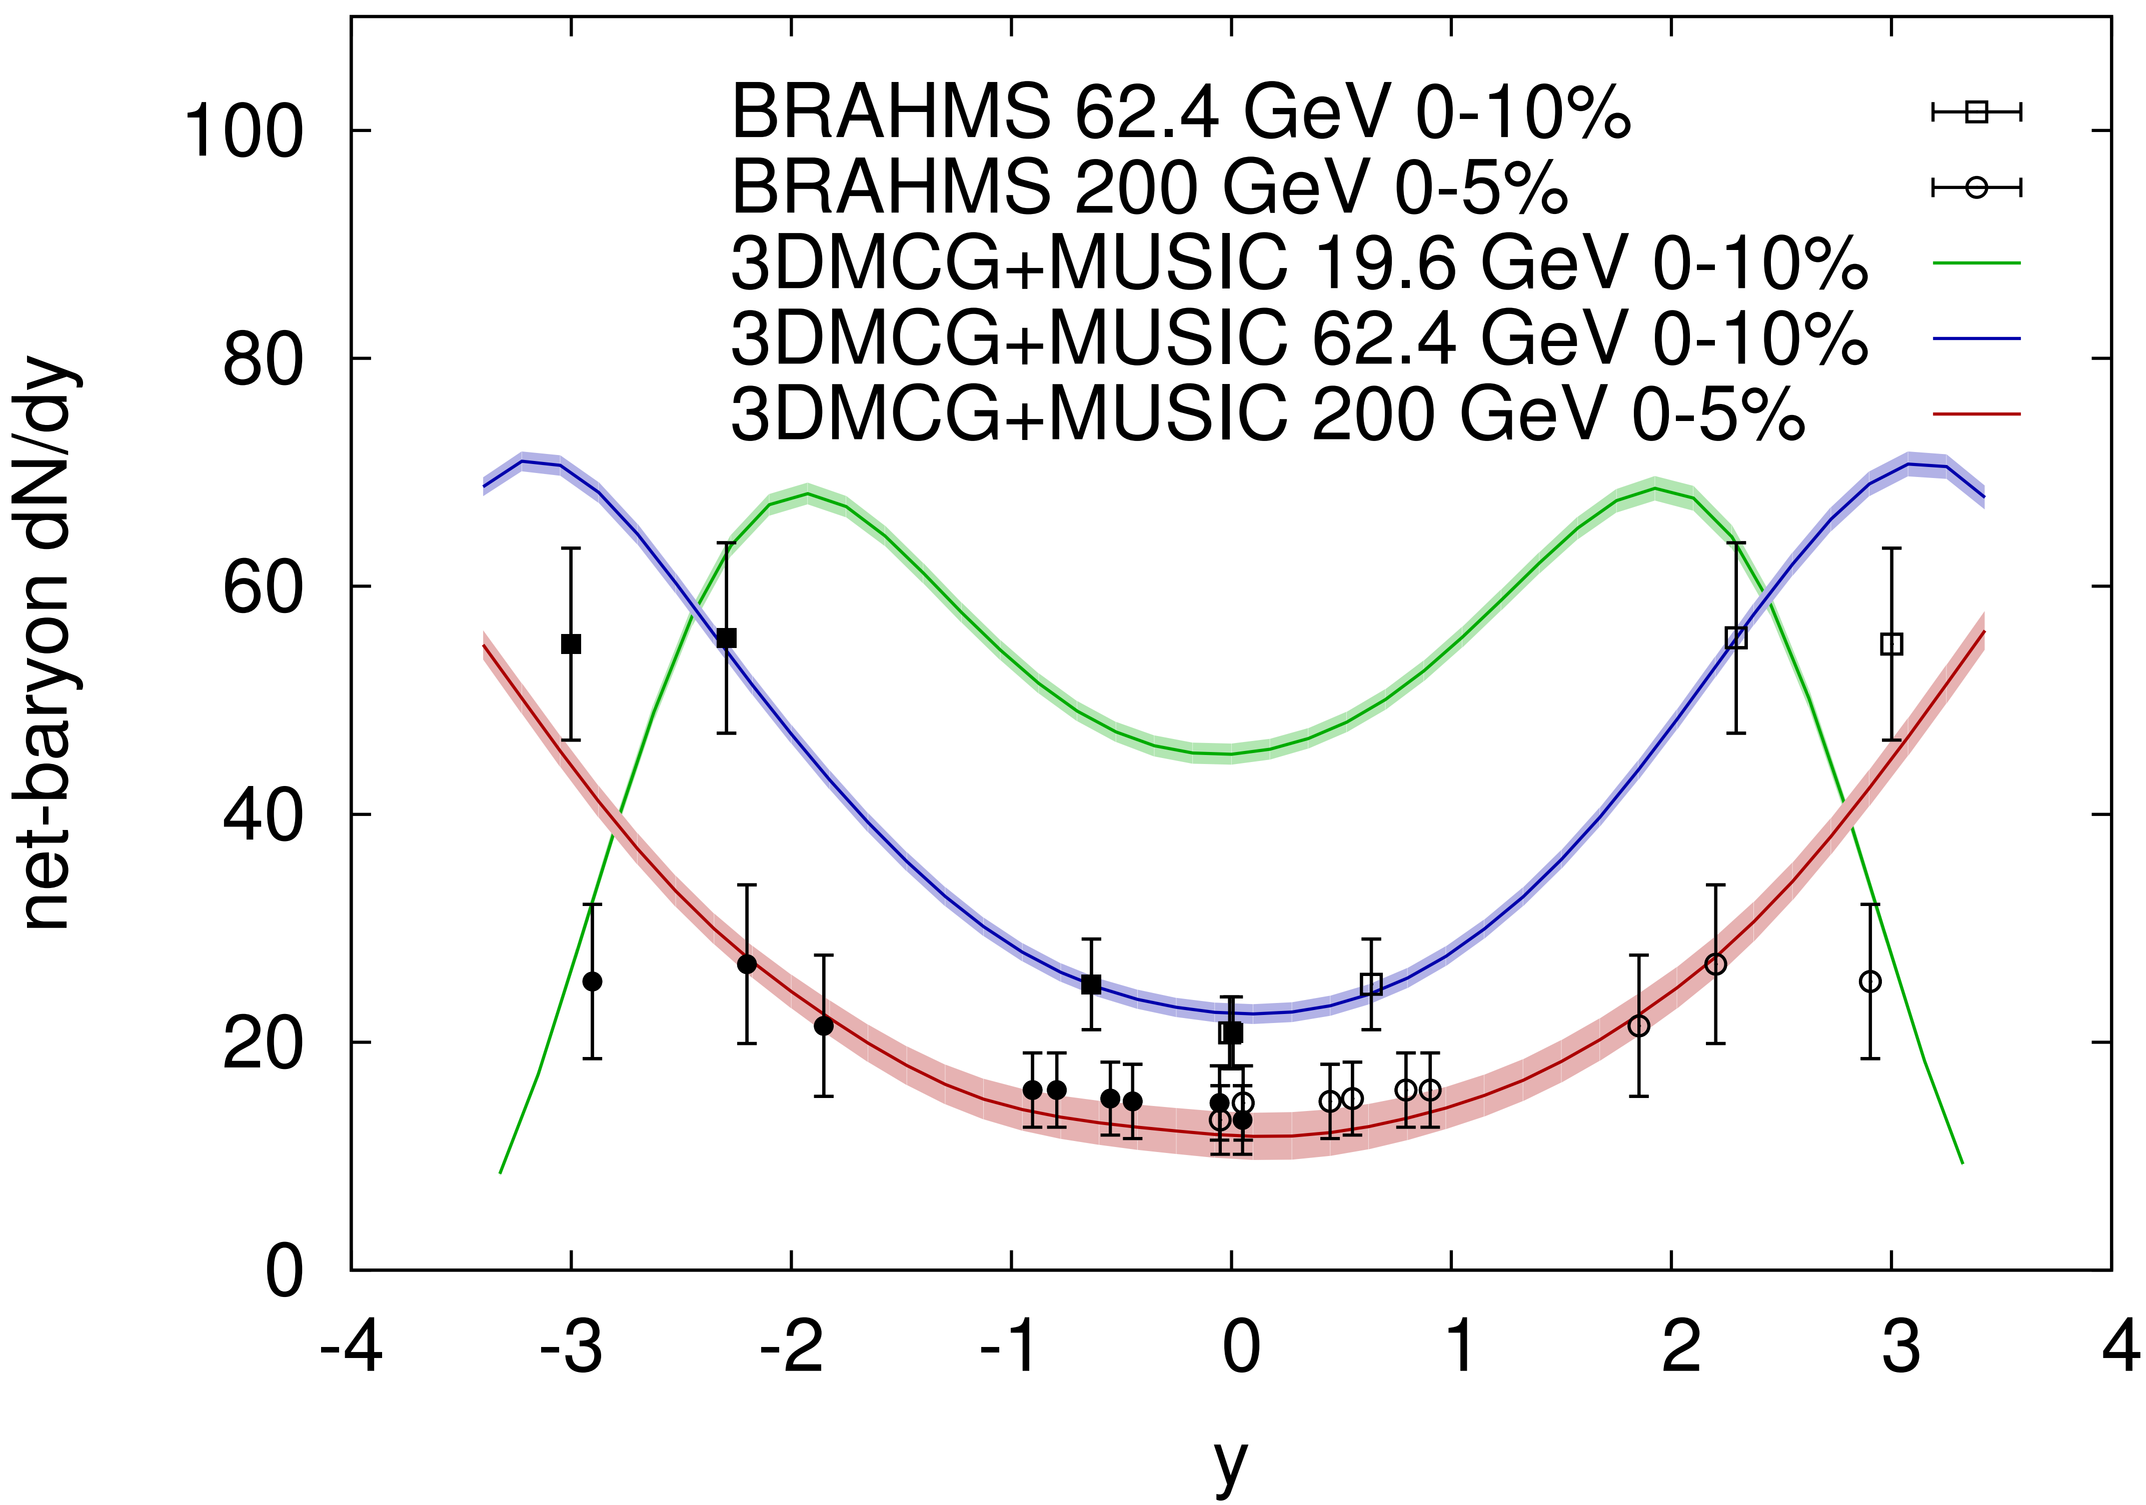






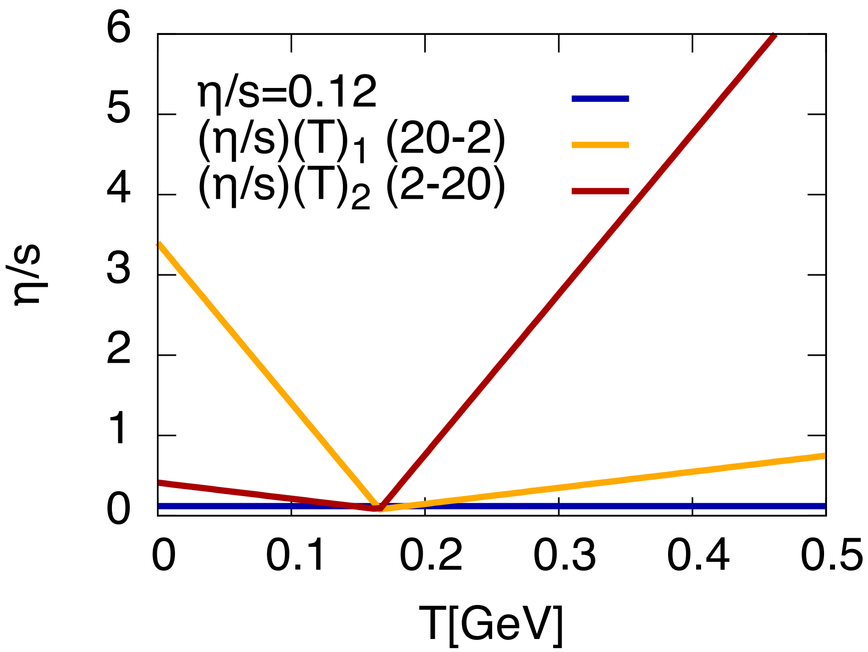
PHOBOS, Phys. Rev. C 83, 024913 (2011)

Net-baryon rapidity distributions



BRAHMS Phys. Lett. B677, 267-271 (2009), Phys. Rev. Lett. 93, 102301 (2004)

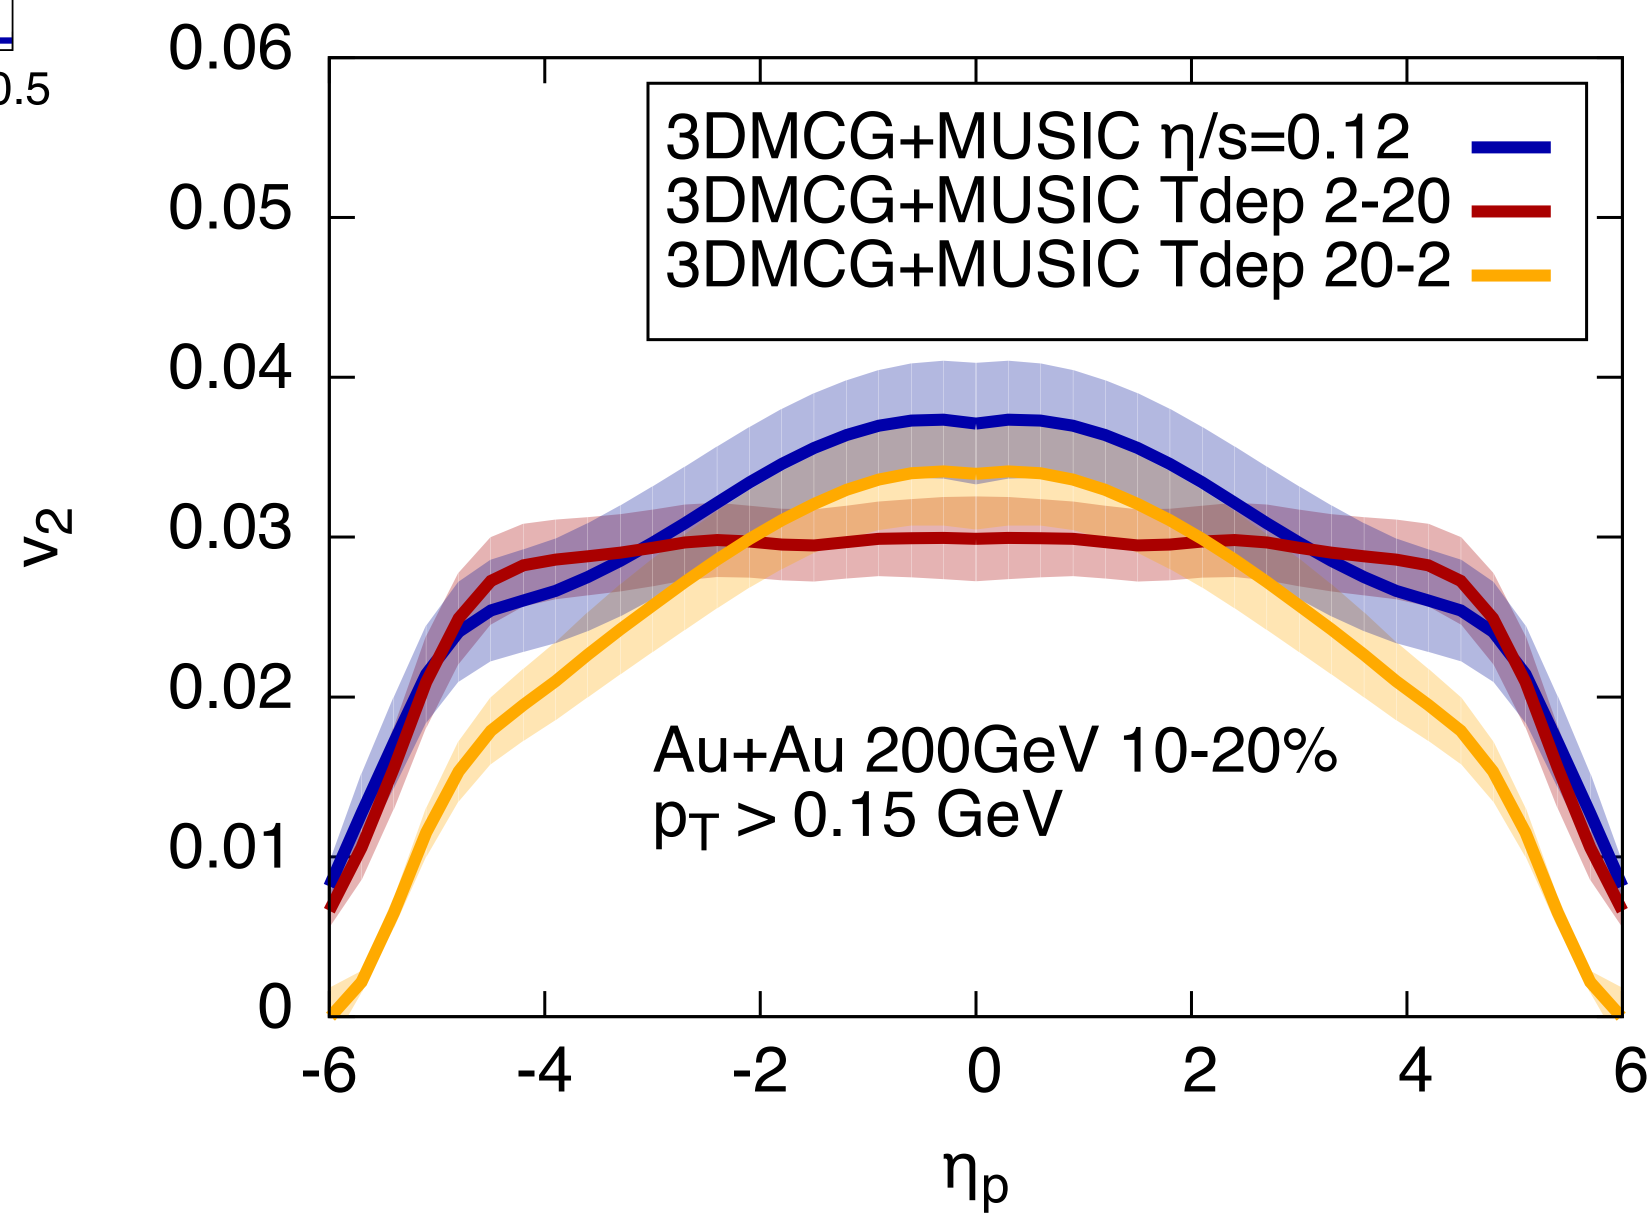
T dependent η/s from rapidity dependence



Numbers (a,b) are the slopes in [GeV^{-1}] in:

$$(\eta T/(\varepsilon + P))(T) = 0.08 + a(T_c - T)\theta(T_c - T) + b(T - T_c)\theta(T - T_c)$$

where $T_c(\mu_B)$

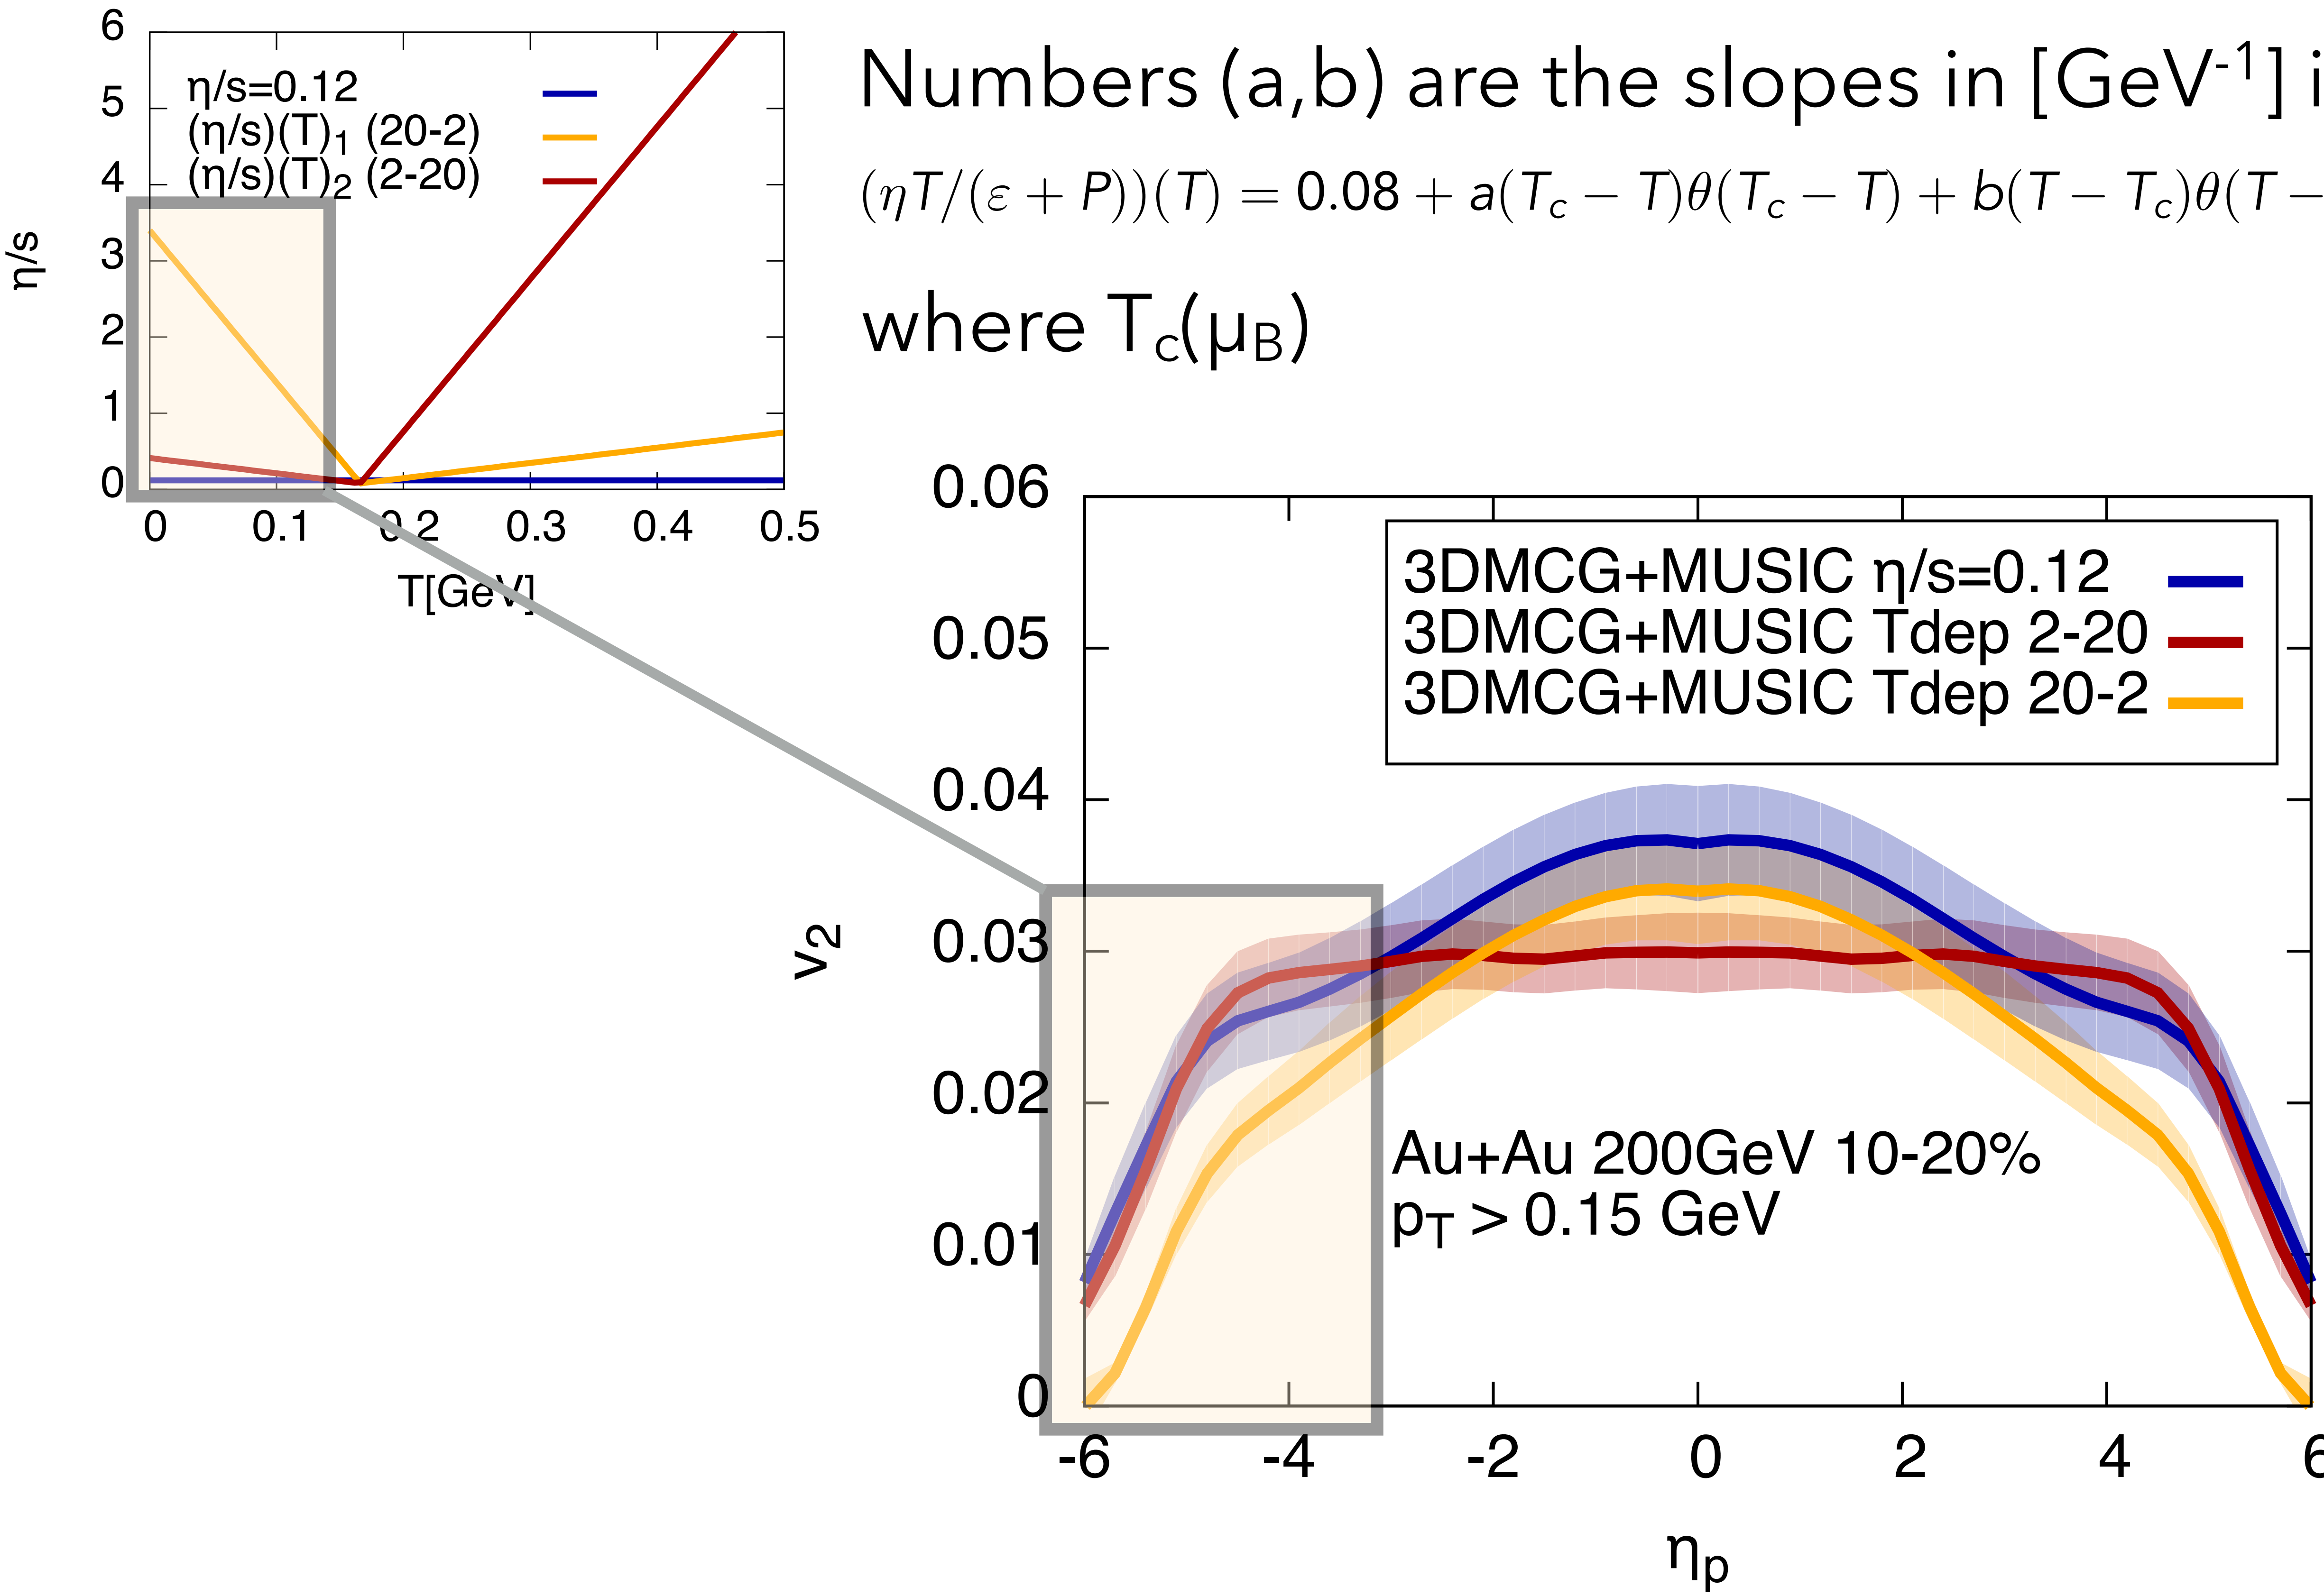


T dependent η/s from rapidity dependence

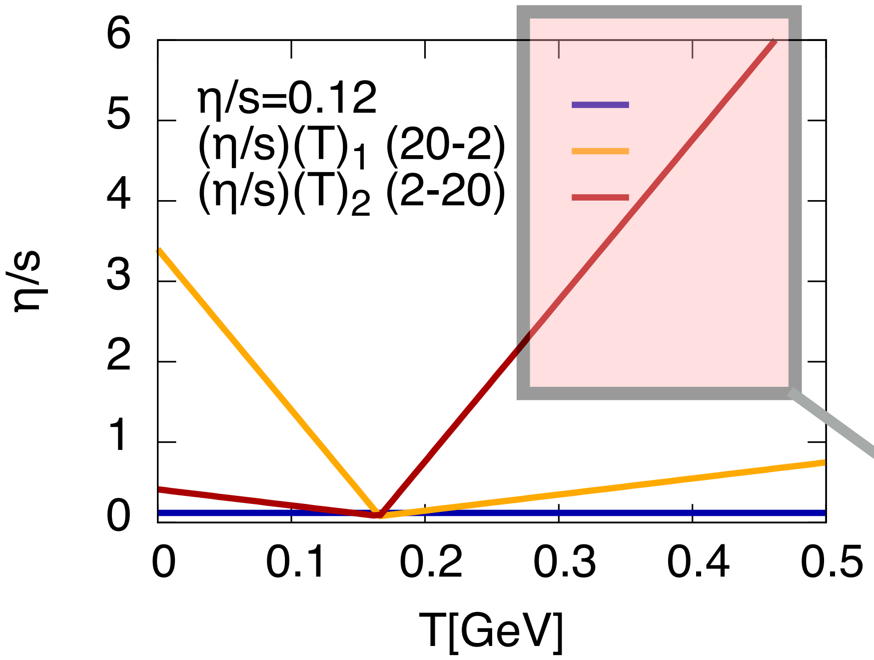
Numbers (a,b) are the slopes in [GeV^{-1}] in:

$$(\eta T/(\varepsilon + P))(T) = 0.08 + a(T_c - T)\theta(T_c - T) + b(T - T_c)\theta(T - T_c)$$

where $T_c(\mu_B)$



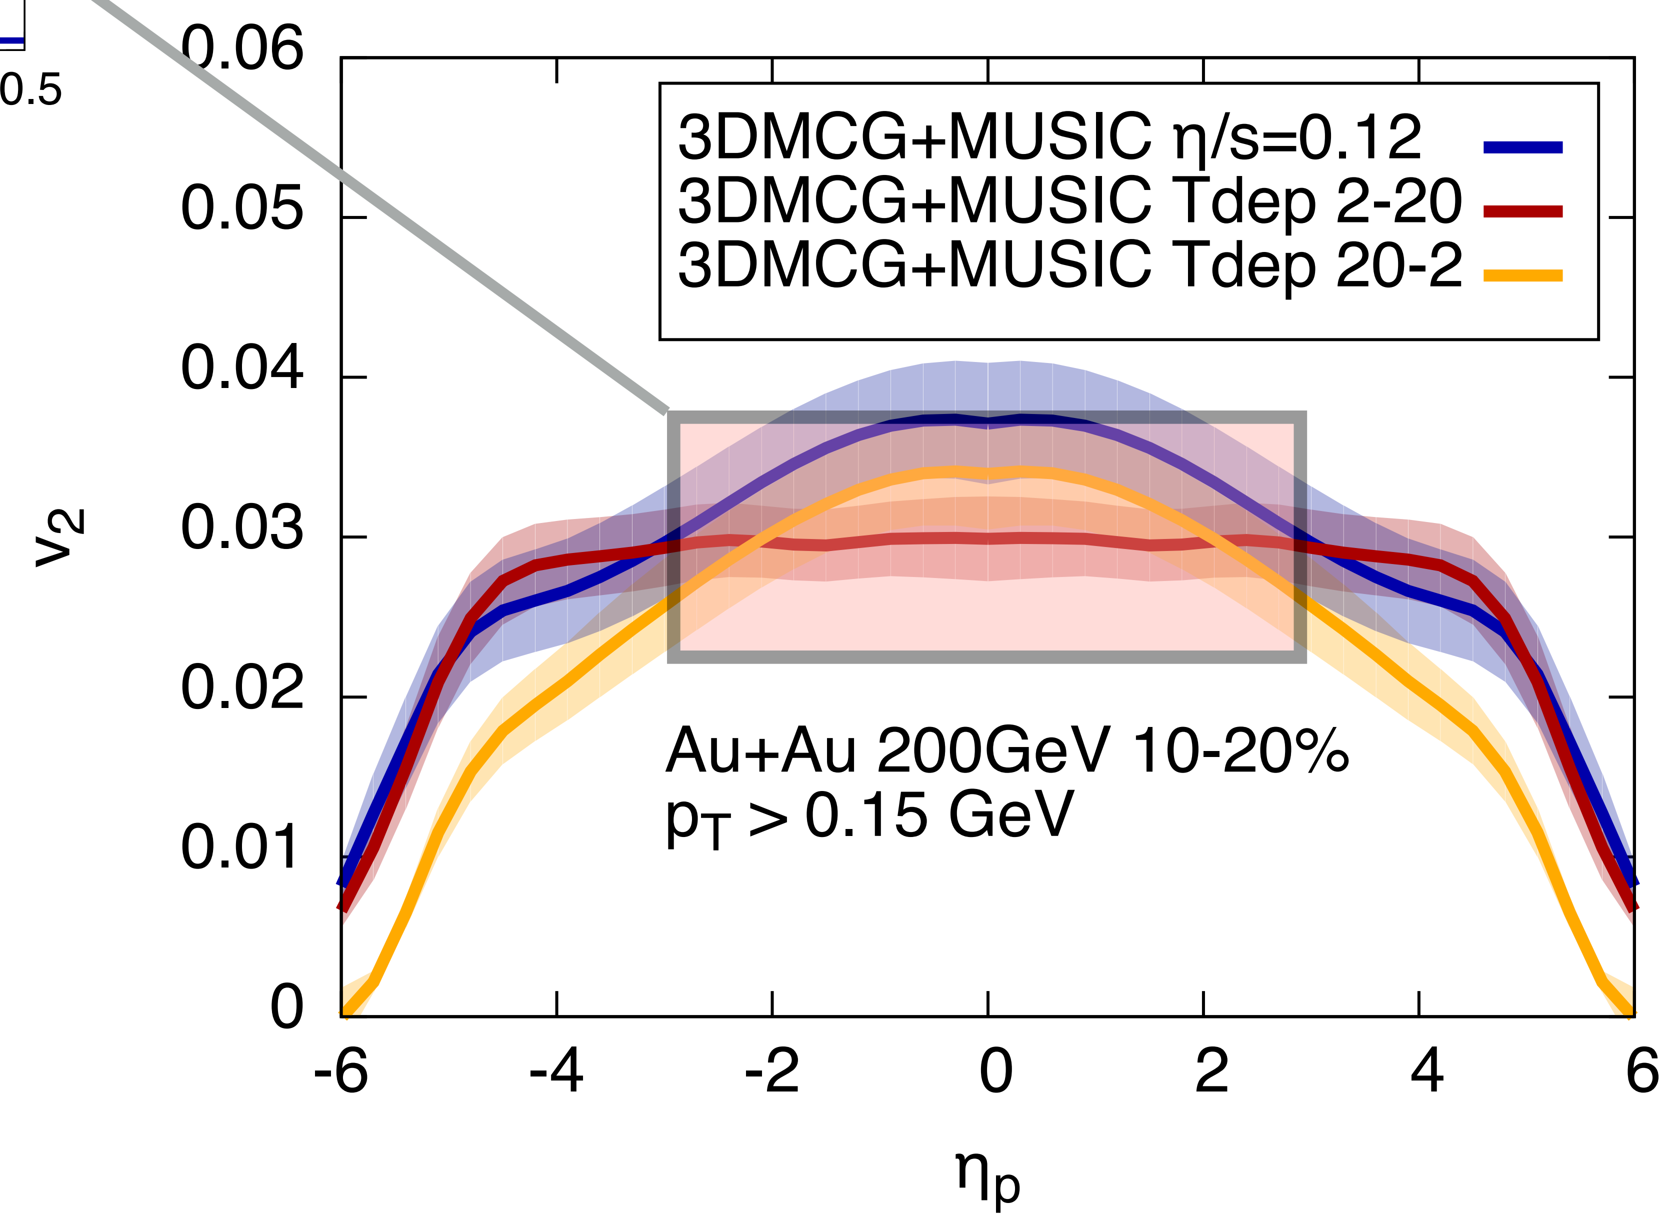
T dependent η/s from rapidity dependence



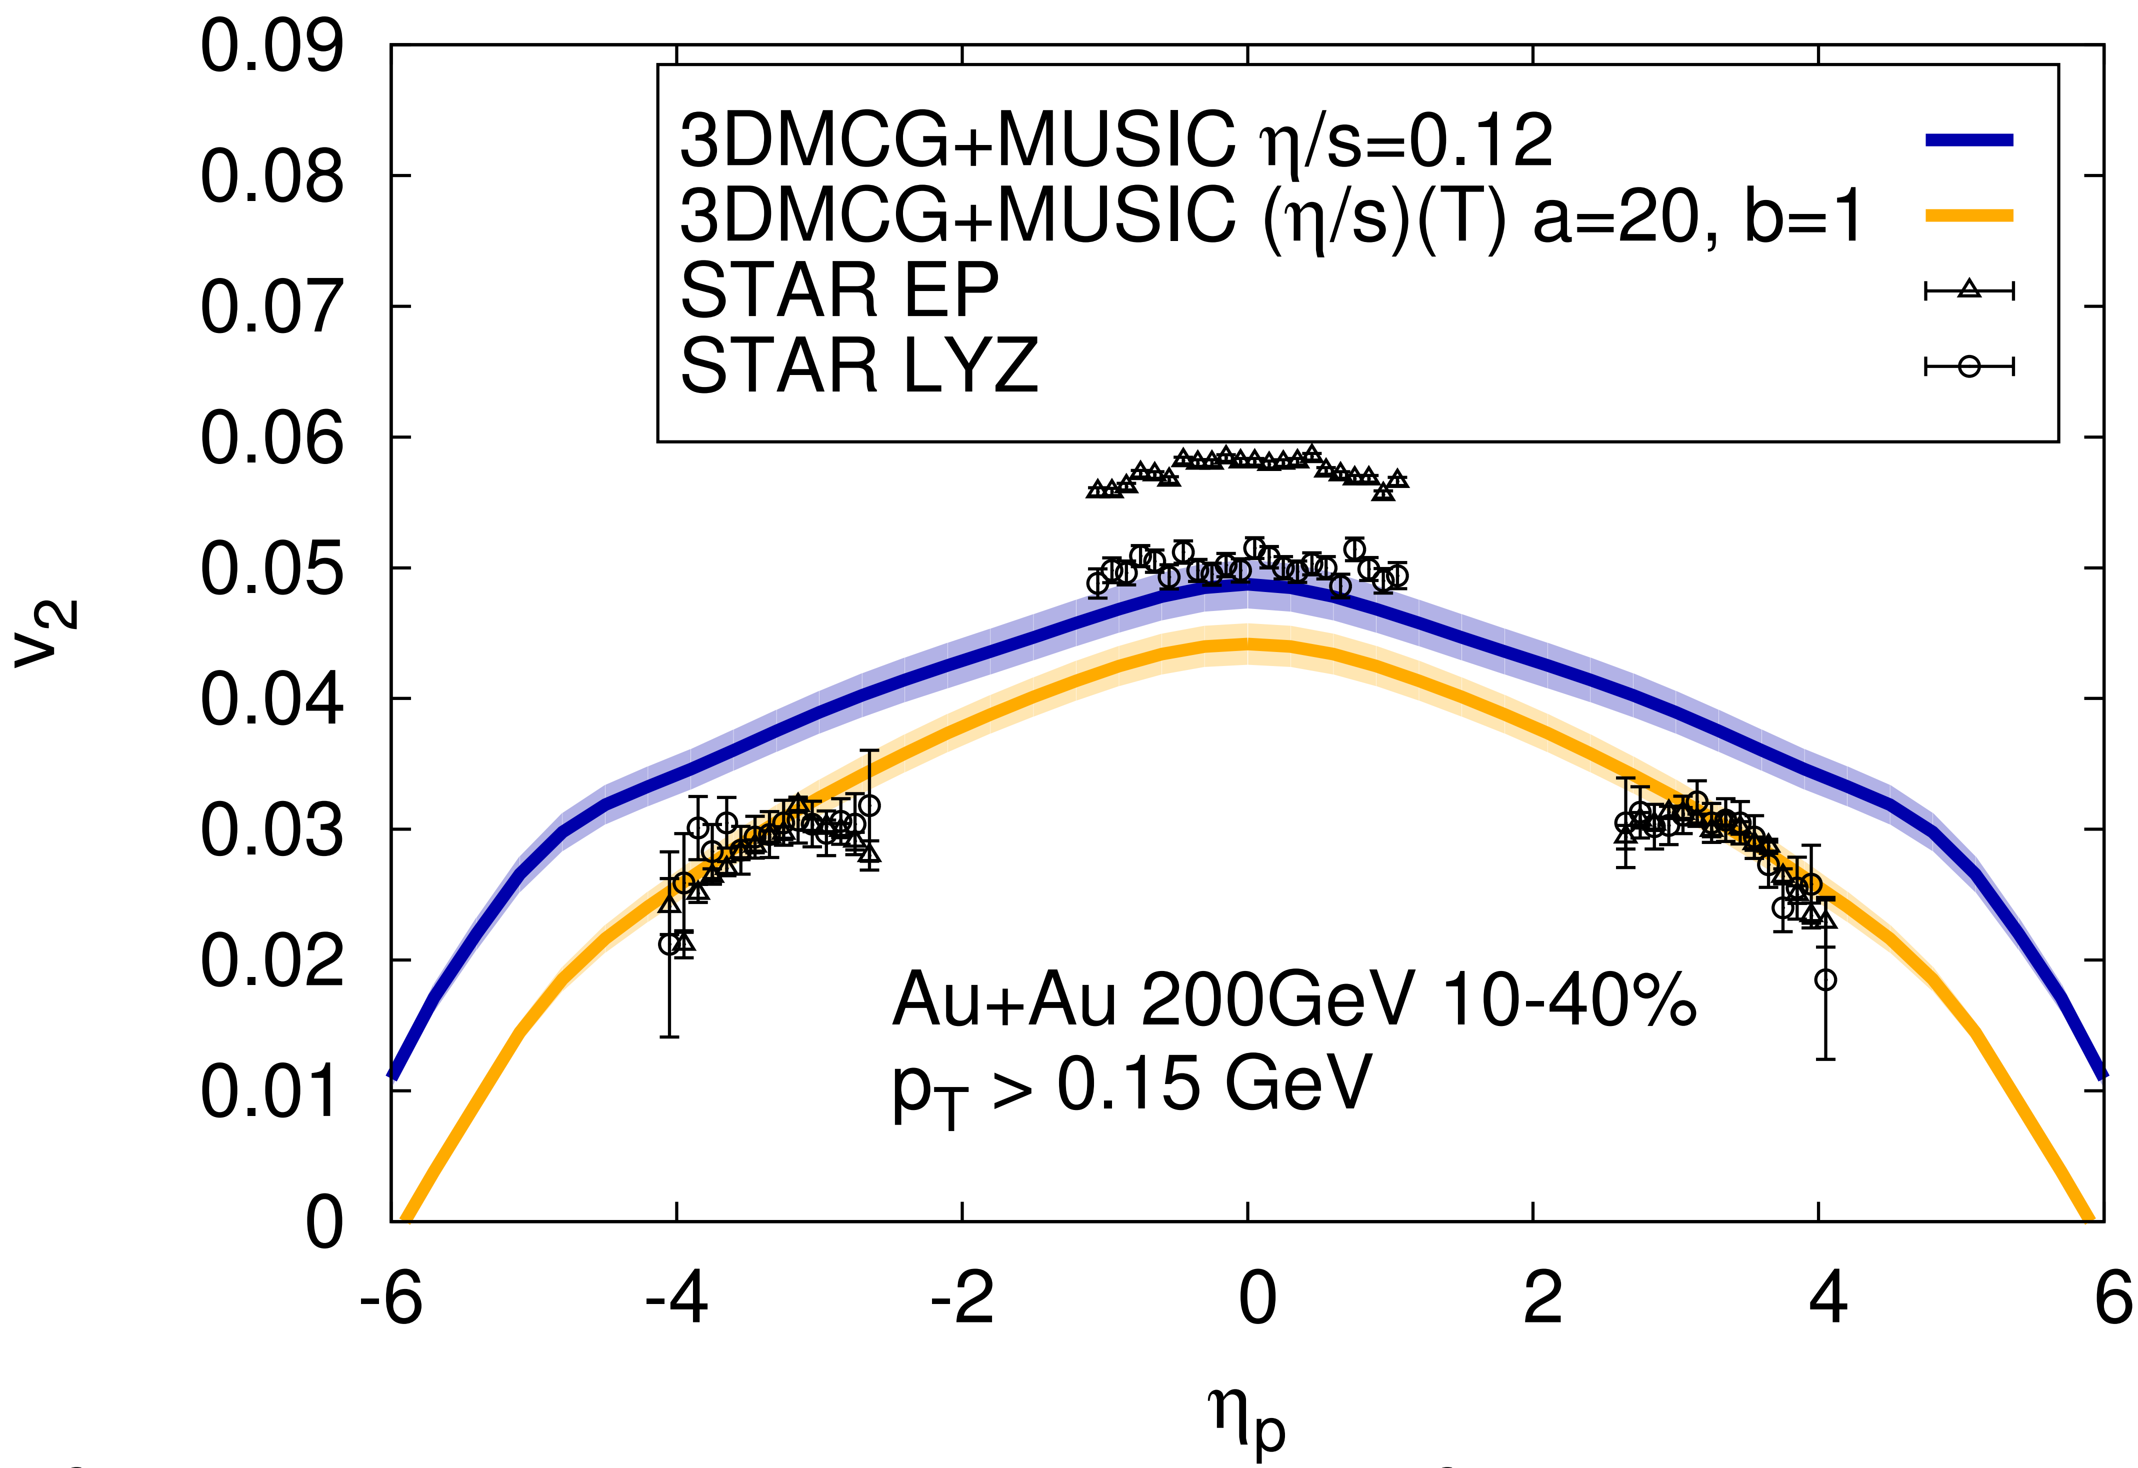
Numbers (a,b) are the slopes in [GeV^{-1}] in:

$$(\eta T/(\varepsilon + P))(T) = 0.08 + a(T_c - T)\theta(T_c - T) + b(T - T_c)\theta(T - T_c)$$

where $T_c(\mu_B)$



Pseudo-rapidity dependent flow



Data favors large hadronic η/s. No room for large QGP η/s.

STAR Collaboration, Phys. Rev. C77, 054901 (2008)

Two-particle pseudo-rapidity correlations

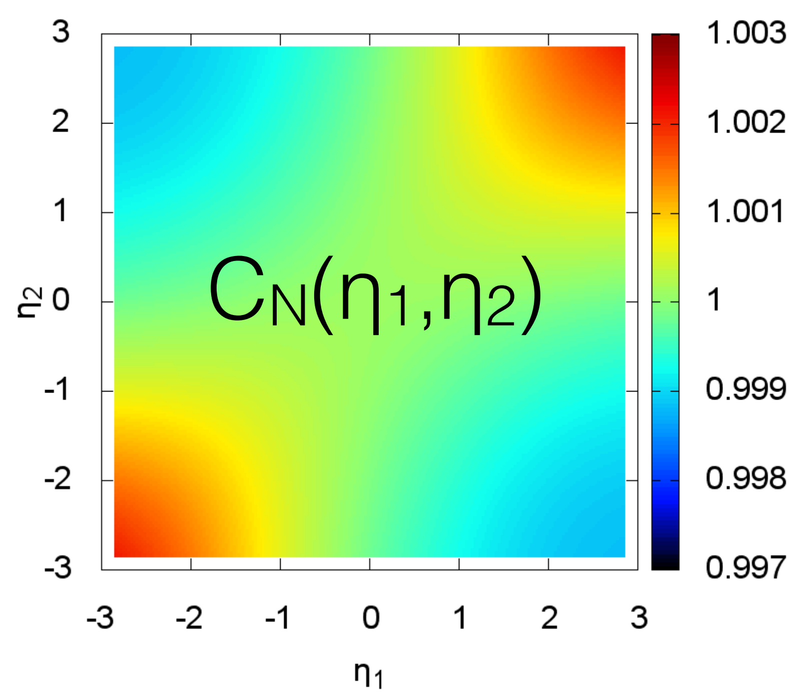
$$C(\eta_1, \eta_2) = \frac{\langle N(\eta_1) N(\eta_2) \rangle}{\langle N(\eta_1) \rangle \langle N(\eta_2) \rangle}$$

to remove the effect of a residual centrality dependence in 5% bin

$$C_N(\eta_1, \eta_2) = \frac{C(\eta_1, \eta_2)}{C_p(\eta_1) C_p(\eta_2)}$$

with

$$C_p(\eta_{1/2}) = \frac{1}{2Y} \int_{-Y}^{Y} C(\eta_1, \eta_2) d\eta_{2/1}$$



Expand in Legendre polynomials. The coefficients are given by

$$a_{n,m} = \int C_N(\eta_1, \eta_2) \frac{T_n(\eta_1) T_m(\eta_2) + T_n(\eta_2) T_m(\eta_1)}{2} \frac{d\eta_1}{Y} \frac{d\eta_2}{Y}$$

also see P. Bozek, W. Broniowski, A. Olszewski, arXiv:1509.04124

Conclusions

- 3+1D viscous relativistic fluid dynamics with fluctuations of baryon number and entropy density in all three dimensions
- Lattice equation of state at finite μ_B implemented
- Rapidity and energy dependence of flow harmonics contains information on transport coefficients' T and μ_B dependence
- Two particle rapidity correlations contain information on the number of sources; are sensitive to short range correlations
- Net-baryon rapidity correlations can shed more light on baryon stopping: Measure them!

Backup

Constructing the equation of state (EoS)

Taylor Expansion

Cannot deal with complex Fermion determinants on lattice, so Taylor expand around zero baryon chemical potential

$$\frac{P}{T^4} = \frac{P_0}{T^4} + \frac{1}{2}\chi_B^{(2)}\left(\frac{\mu_B}{T}\right)^2 + \frac{1}{4!}\chi_B^{(4)}\left(\frac{\mu_B}{T}\right)^4 + \mathcal{O}\left[\left(\frac{\mu_B}{T}\right)^6\right]$$

because of matter-anti-mater symmetry only even powers appear
similarly for energy density and entropy density

For net-baryon density we have

$$\frac{n_B}{T^3} = 0 + \chi_B^{(2)}\frac{\mu_B}{T} + \frac{1}{3!}\chi_B^{(4)}\left(\frac{\mu_B}{T}\right)^3 + \mathcal{O}\left[\left(\frac{\mu_B}{T}\right)^5\right]$$

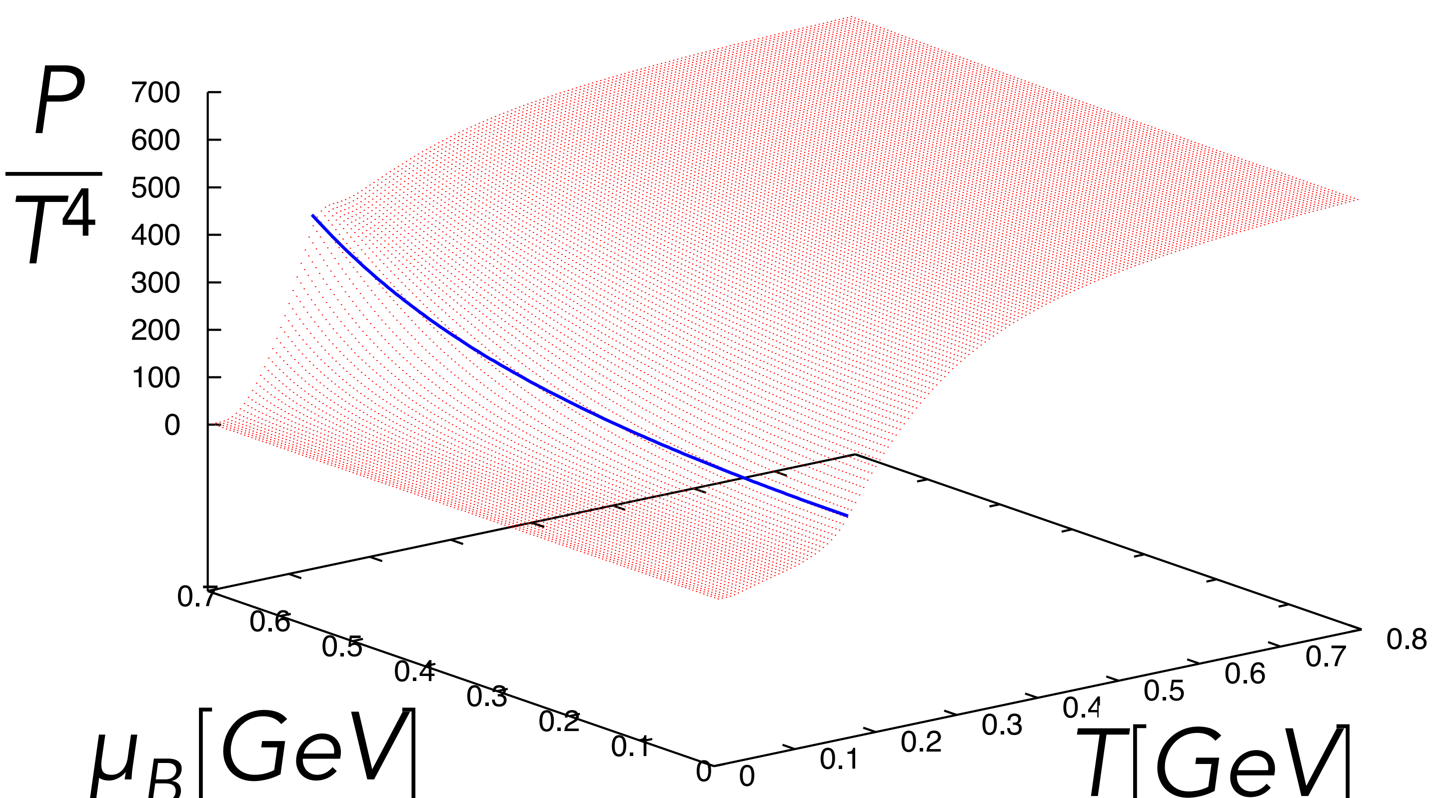
Constructing the equation of state (EoS)

Smooth matching (cross over)

As a first try, we match the HRG and lattice EoS smoothly

$$\frac{P}{T^4} = \frac{1}{2}\left[1 - \tanh\frac{T - T_C(\mu_B)}{\Delta T_C}\right]\frac{P_{\rm HRG}(T)}{T^4} + \frac{1}{2}\left[1 + \tanh\frac{T - T_C(\mu_B)}{\Delta T_C}\right]\frac{P_{\rm lat}(T_s)}{T_s^4}$$

In the future one can introduce a critical point here.



T_C: connecting temperature

ΔT_C: width of overlap area

T_s: temperature shift

$$T_s = T + d[T_C(0) - T_C(\mu_B)]$$

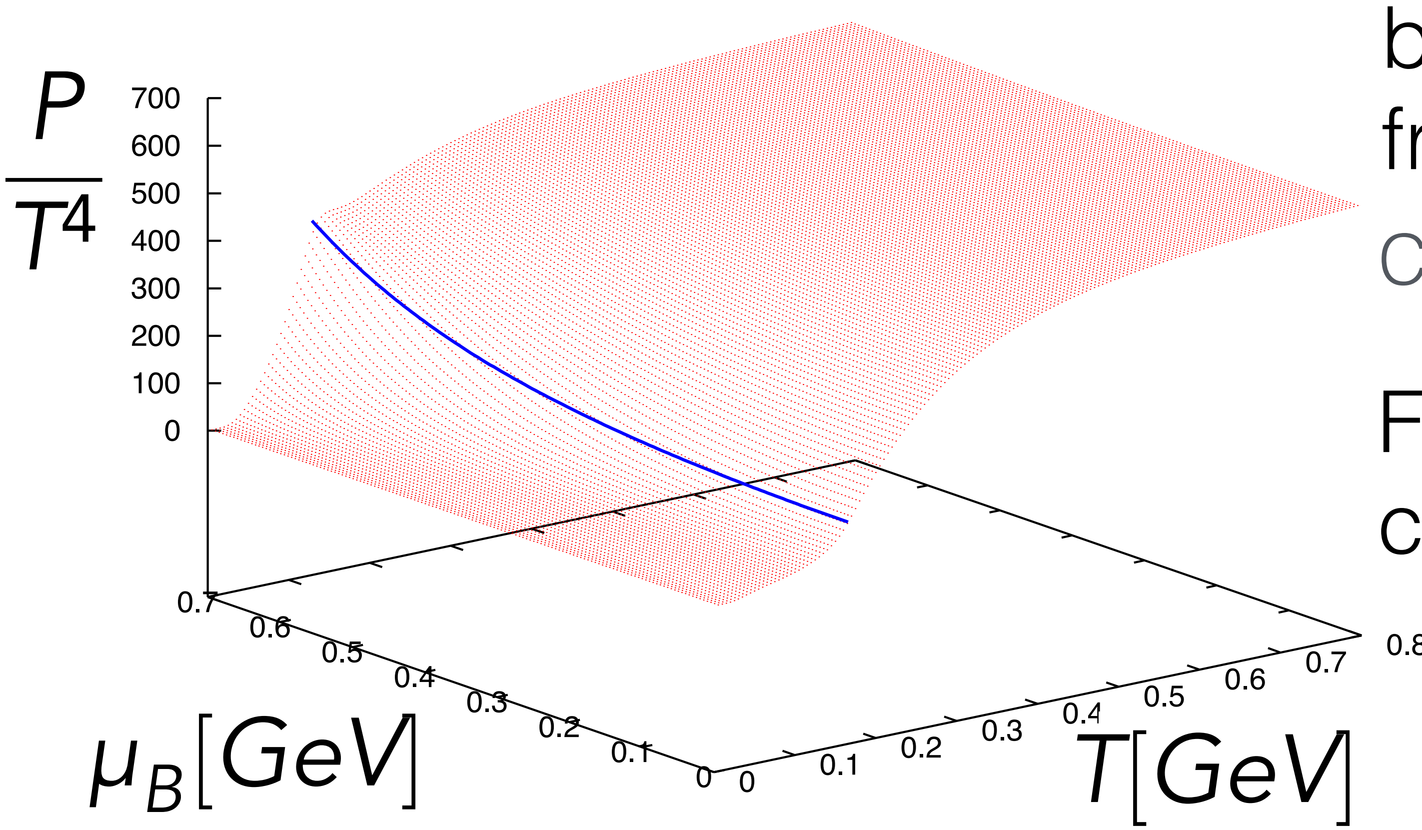
Constructing the equation of state (EoS)

Smooth matching (cross over)

As a first try, we match the HRG and lattice EoS smoothly

$$\frac{P}{T^4} = \frac{1}{2}\left[1 - \tanh\frac{T - T_C(\mu_B)}{\Delta T_C}\right]\frac{P_{\rm HRG}(T)}{T^4} + \frac{1}{2}\left[1 + \tanh\frac{T - T_C(\mu_B)}{\Delta T_C}\right]\frac{P_{\rm lat}(T_s)}{T_s^4}$$

$$T_C(\mu_B) = 0.166\,\mathrm{GeV} - c(0.139\mu_B^2 + 0.053\mu_B^4)$$



based on the chemical freeze-out line (c=1)

Cleymans et al, PRC73, 034905 (2006)

For the connecting line we use c=d=0.4, ΔT_C=0.1 $T_C(0)$

Constructing the equation of state (EoS)

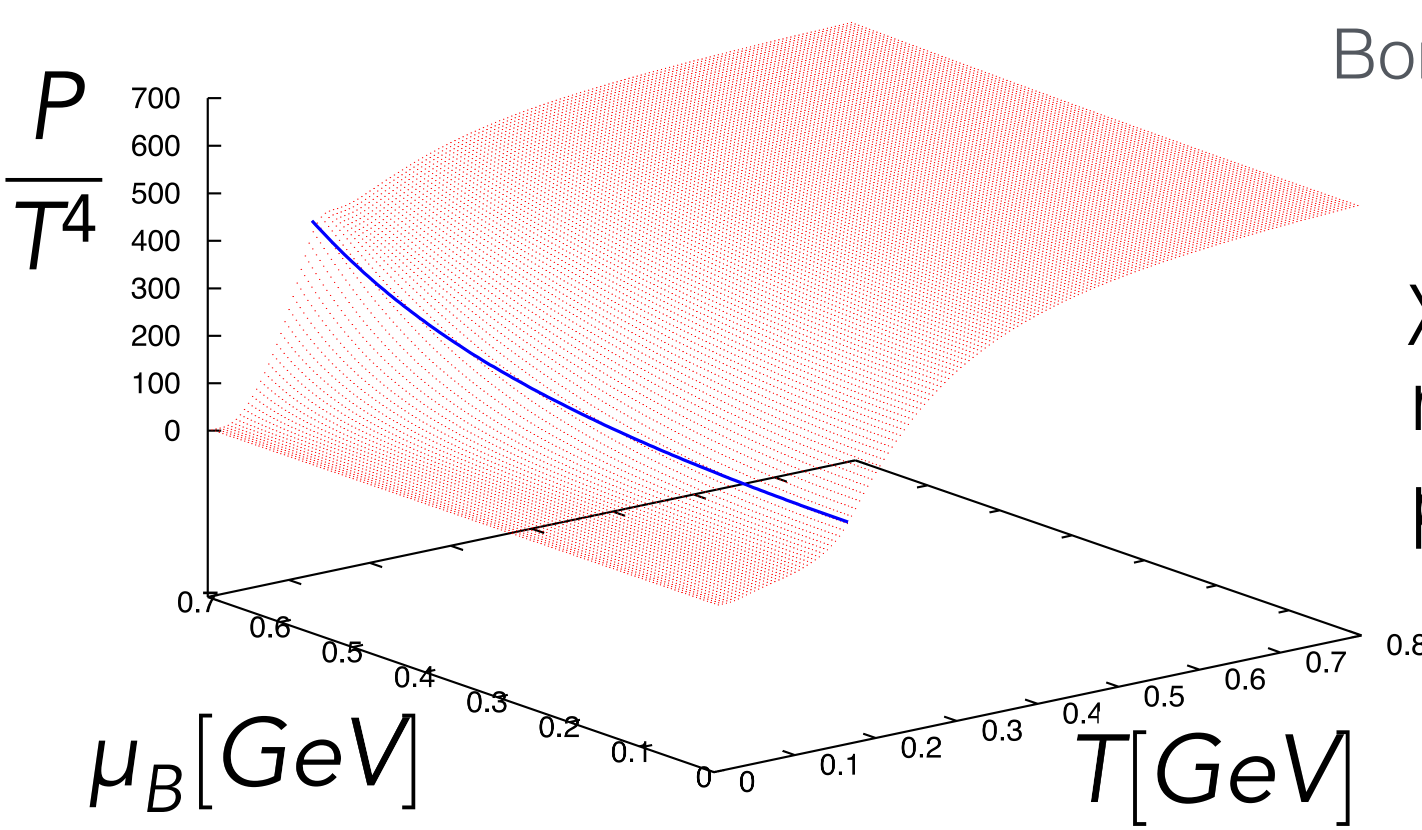
Smooth matching (cross over)

As a first try, we match the HRG and lattice EoS smoothly

$$\frac{P}{T^4} = \frac{1}{2}\left[1 - \tanh\frac{T - T_C(\mu_B)}{\Delta T_C}\right]\frac{P_{\rm HRG}(T)}{T^4} + \frac{1}{2}\left[1 + \tanh\frac{T - T_C(\mu_B)}{\Delta T_C}\right]\frac{P_{\rm lat}(T_s)}{T_s^4}$$

Parameters P_0^{lat} and $\chi_B^{(2)}$ are determined from the lattice:

Borsanyi et al, JHEP1011, 077 (2010)
Borsanyi et al, JHEP1201, 138 (2012)



$\chi_B^{(4)}$ is obtained from the ratio $\chi_B^{(4)}/\chi_B^{(2)}$ in a HRG and parton gas model

δf corrections in the presence of net baryons

A. Monnai, T. Hirano, PRC80, 054906 (2009); Nucl. Phys. A847, 283 (2010)

Grad's 14 moment method

$$\delta f^i = -f_0^i(1 \pm f_0^i)(b_i \underbrace{\varepsilon_\mu^B}_{4} p_i^\mu + \underbrace{\varepsilon_{\mu\nu}}_{10} p_i^\mu p_i^\nu)$$

particle i's baryon quantum number

ε_μ^B and $\varepsilon_{\mu\nu}$ are determined by the self-consistency conditions

$$\delta T^{\mu\nu} = \sum_i \int \frac{g_i d^3p}{(2\pi)^3 E_i} p_i^\mu p_i^\nu \delta f^i = -\Pi\Delta^{\mu\nu} + \pi^{\mu\nu}$$

$$\delta N_B^\mu = \sum_i \int \frac{b_i g_i d^3p}{(2\pi)^3 E_i} p_i^\mu p_i^\nu \delta f^i = \cancel{V_B^\mu} \; =0$$

(no baryon diffusion)

δf corrections in the presence of net baryons

A. Monnai, T. Hirano, PRC80, 054906 (2009); Nucl. Phys. A847, 283 (2010)

Grad's 14 moment method

$$\delta f^i = -f_0^i(1 \pm f_0^i)(b_i \varepsilon_\mu^B p_i^\mu + \varepsilon_{\mu\nu} p_i^\mu p_i^\nu)$$

After tensor decomposition and one finds

$$\varepsilon_\mu^B = D_\Pi \Pi u_\mu$$

$$\varepsilon_{\mu\nu} = (B_\Pi \Delta_{\mu\nu} + \tilde{B}_\Pi u_\mu u_\nu)\Pi + B_\pi \pi_{\mu\nu}$$

where the coefficients are computed in kinetic theory

We parametrize them as functions of T and μ_B
Note: Results of net baryon density are very sensitive to accuracy of the bulk-δf parametrization
